

PROJECT

1

HOST A WEBSITE ON AMAZON S3

STORAGE SERVICE

Prepared by:
Amrize JK
Certified Solutions Architect Associate

Objective

This project teaches you how to host a static website using Amazon S3, allowing users to access your site via a public URL.

You'll learn to upload content, configure S3 for web hosting, and control public access permissions.

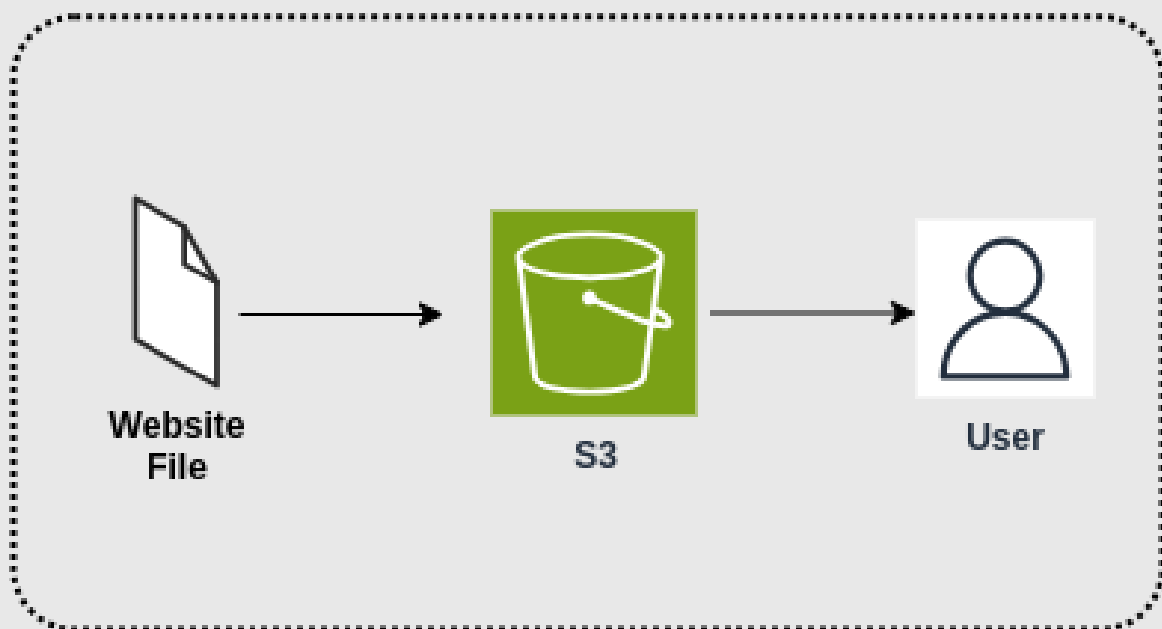

Services

Amazon S3 - Stores and delivers your website files like HTML, CSS, and JavaScript to users via the internet.

S3 Bucket Policy - Controls and grants public read access to the files stored in your S3 bucket.

Static Website Hosting (S3 Settings) - Enables your S3 bucket to function as a static website by specifying index and error pages.

Architecture Diagram

Website files like HTML, CSS, and JavaScript are uploaded to an S3 bucket. The bucket is configured for static website hosting, and permissions are set to allow public read access. Once hosted, users can access the site via the S3 generated endpoint URL directly from their browser.

Steps to Implement

1. Create an S3 Bucket:

Go to the Amazon S3 console and click on “Create bucket.” Enter a globally unique bucket name (e.g., my-static-site-demo) and choose the region closest to your users. Keep the rest of the default settings, but uncheck “Block all public access” to allow public visibility. Click “Create bucket” to proceed.

2. Upload Website Files:

Open your newly created S3 bucket and click “Upload.” Add your static website files including index.html, style.css, and any images or scripts. Click “Upload” again to store them in the bucket. Ensure the file structure is correct, with your index.html at the root if it’s a single page site.

3. Configure Static Website Hosting:

Inside the bucket, go to the “Properties” tab and scroll to “Static website hosting.” Enable the feature and set index.html as the index document. You can also specify error.html if needed. Save the settings to activate hosting, and note the S3 endpoint URL provided.

4. Set Bucket Policy for Public Access:

Go to the “Permissions” tab and click on “Bucket policy.” Paste a public read access policy allowing everyone to view files in your bucket. Save the policy. Now your site can be accessed publicly through the endpoint URL you received in the previous step.

Story Time

Amazon S3 (The Festival Stage):

Think of Amazon S3 as the grand festival stage where your entire show (website) is set up. All your banners, props, and scripts, aka HTML, CSS, and JS files, are placed neatly on the stage, ready for the audience (users) to enjoy the performance.

S3 Bucket Policy (The Festival Guard's Scroll):

This is the guard's scroll of rules that says who's allowed into the festival. Without the right scroll (policy), the gates stay closed. But once you write the right lines, the guard happily lets in every visitor to view the website celebration.

Static Website Hosting (The Magic Spotlight):

Turning on static website hosting is like switching on the magic spotlight that makes your stage visible to the whole town. With this spotlight, the festival goes live, and people can join just by clicking the enchanted portal link (S3 endpoint)!
